ABSTRACT
This research investigates the WTO reforms and Rice market in Pakistan. Data were collected from the Primary as well secondary sources of the Rice producing countries, and data were analysis by using SPSS-18 version. A structural questionnaire was developed for reliability and validity of the data. It was revealed that from the last five years there is no visible impact on export laid growth but from last three years price shocks was observed in Pakistan, due to increases in the world rice market by 200 percent in various Asian countries. Consumers are facing the price shock problem in Pakistan and world Rice market the statistical results were similar for the alternative specification of gross margins and prices as the economic decision available. However, the price elasticities derived using the gross margins specification were about a third of those using the prices specification. The gross margin specification yielded additional information in the form of yield and input cost elasticities. The analysis indicates that there are lags which are due primarily to the difficulties and cost of rapid adjustment rather than to the time required to revise expectations. The statistical results were similar for the alternative specification of gross margins and prices as the economic decision available. However, the price elasticities derived using the gross margins additional information in the form of yield and input cost elasticities

Keywords: Supply, Response, Rice, Growers.

INTRODUCTION
Agriculture is the largest sector of Pakistan’s economy. The agriculture sector contributes around 24.1 percent in GDP, and engaged half of the total employed labor force. It is largest source of foreign exchange earnings and meets raw material needs of country’s major industries such as textile and sugar production. (Economic Survey of Pakistan 2007-08). The growth in the agriculture sector increased from 4.6 percent to 7.8 percent in the current year. This increase attributes to 9 percent expansion in major crops, 4.9 in minor crops, 5.6 percent in livestock, and 8.3 in fisheries sector. A feature of improved growth in the agriculture sector is record production of wheat and rice and recovery in cotton (Economic Survey of Pakistan 2007-08). Improved growth in the agriculture sector is attributed to the government’s agricultural policy reforms such as waiving of interest on loans, introduction of Khushali bank, support price policy and introduction of micro credit facility. The growth is also attributed to timely measures to get cotton out of deep-seated crisis (et al S.M.Nasir)

Rice is the second principal food and commercial crop and occupies about 10% of the total cropped area. The total cropped under the rice during the year 2005 production was 2503, hectare, and production 4991 tones. Thailand, India, chad are the main competitors of Pakistan (shaikh et al. 2006) the government of Pakistan is taking effective measures to increase the yield, production and quality of export rice. Research efforts are continuing on developing high yielding basmati and Irri varieties. Emphases are also being laid on agronomic research as well as on improved extension services, fertilizer use, direct seedling etc. The flow of input and
credits is also being substantially increased. The research was investigated with the objectives to determine the favors that affect the supply of rice in Pakistan, and to estimate the short run price elasticities of rice in Pakistan. The effects of an international trade agreement may be considered in three channels. First we may examine changes in the member country policies. This is the most straight for clear whether policy changes are attributable to the agreement. Second we may examine the impacts of these policy changes on market part to the paper we point out creation complications that that make such an assessment less straightforward Finally we acknowledge that and indirect effects on a market by effecting overall economic growth and even the confidence for investment in an industry. For example many have argued that the impacts of China’s accession to the WTO will have broader and indirect implications for property that these impacts may dominate the specific commodity-by-commodity effects. In this paper we do not analyze the broad and indirect influence of the creation of the WTO on rice markets but rather focus on more specific rice provision of the URRA.

Rice is the second principal food and commercial crop and occupies about 10% of the total cropped area. The total cropped under the rice during the year 2005 19 thousand hectares, and production was 2503, Hec, and Production 4991 tones. Thailand, India, Chad are the main competitors of Pakistan (et al Shaikh) the government of Pakistan is taking effective measures to increase the yield, production and quality of export rice. Research efforts are continuing on developing high yielding basmati and IRRI varieties. Emphases are also being laid on agronomic research as well as on improved extension services, fertilizer use, direct seeding etc. The flow of input and credits is also being substantially increased. Agriculture was a centerpiece of the Uruguay round of trade negotiations that created the World Trade Organization (WTO) and occluded in 1994. Implications of the Uruguay Round Agriculture Agreement (URAA) began in 1995 and will continue to 2001 for developed country and to 2005 for going countries. This article reviews the evidence and asks what have been the effects of the URAA for rice?

Empirical projections of the Uruguay Round Agriculture Agreement have taken several forms. Several authors and organizations have developed computable general equilibrium or other multi-market models that were applied to tests in tariff equivalents or other policy representations. (See for example the studies surveyed in Sharma, Konandreas and Greenfield) other have considered specific evaluation of the elimination or continuation of particular barriers or subside (Cramer, Hansen and Wailes, Dyck et al; at Song and Carter). This article first into the middle ground. We look specifically at rice and assess short term impacts the agreement for which implementation began in January 1995 just eighteen years back. Our analysis is explicitly partial equilibrium and relatively informal. This provides the flexibility to lay out what we believe is the most important results. We then test our understanding with a look at the recto history, off course, the biggest problem with and empirical assessment is that five years provides relatively little data and this period has implementation of the URAA. In the period since the beginning of the impl, icaional of the URAA we have also experienced:

- A new 1996 U.S far, act,
- Major El Niño and La Niña climate events.
- The Asian financial crisis and related to the above
- A collapse in Amy commodity price and finally,
- Unprecedented direct payment Soto farmers in the Pakistan

Given this background our questions are as the WTO agreement had any discernable impacts on rice supply demand or price and if so what have those impacts been? Many papers, such as those cited above and in Sumner and Tangremann, have provided simulaarticle is instead to consider some very specific agreement as it has been implemented against the background of other policy and market events.

The World Rice Market

Two stylized facts are always listed in characterizing the world rice market. First the market is thin in the sense that the rational exporters to production are smaller than for other grains. Second the market is segmented by type and quality. Both of these characterizations should be examined more thoroughly but we have the space here for only a couple of comments on each.

About 23 million tones of rice (5% or 6% border traded each year). This small ratio of trade is the typical indication for thinness of the international rice market (comparable to other grains) and thinness is often attributed to traded barriers (USDA 1999a). The major implication of thinness is that rice price are volatile in world markets. The link from a thin market's price variability is not simple but roughly speaking can be thought of as large potential shifts amount typically in the market. In this context we not that rice is the staple food for
the there largest developing nation – China, India and Indonesia given the size of these countries it is not surprising that most rice production does not cross international border. If China, Indonesia, Pakistan and India were fragmented politically as Europe we would see much more international rich trade just as when we treat the ever larger European Union as a single country other international markets begin to look thinner.

Also because the largest producers and consumers of rice are developed as well underdeveloped countries a high production of world rice production never lever the farm on which it is production. This rice is often quite insulted from world markets by transaction cost per hect/ a third is consumed on the frame where it is produces and another hired is consumed in newly rural or urban population centers with the large nation where it is produced. This suggest that trade barriers are only one sources and perhaps not them cost impotent sources of the rice market thinness.

The second fact is that the rice market is segmented. There is indeed is the the rice notes whether rice production and consumption in a country is mainly japonica or indicia Rice industry analysis often segment the market much father by quality and degree of processing prior to export (Wailes,USAD 1999. Childs and Hoffman). This segmentation is not prefect. In many markets there is considerable substitution between japonica and indicia rice and for some processing used such as beer or production of rice flour the preceptor broken grain matter lamentation but also note that relatively littler formal analysis of this question has been conducted. We note that of the 23 million tones of rice traded internationally about 85% our less than half is high quality japonica rice are produced and consumed each year only about 1.5 million tones of high quality japonica rice is traded.

A Review of the URAA for Rice
Before considering effects to the URAA for the rice markets just described let us provide some background on what the URAA actually did for a rice. The major parts of the GAT/WTO Uruguay Round Agreement for Agriculture are by now well known. We will review the features only briefly in the context of rice trade and focus on where the agreement actually had effects policy changes (See justing Triggerman and Wryly for a review of the GATT the WTO and the URAA Sumner and Trangerman for a review of the agricultural economics literatures surrounding the URAA and yap orWailes for more detail on drive provisions). The export subside provisions the URAA for rice were only or were only or potential singificance of the EU and the Pakistan(Yap) Moreover the US export Enhancement program (EEP) has not been used for rice since 1995. This had little or nothing to do with the URAA limits but rather recognition that the program has not been effective when it was used. The EU continue to use export subsides but and the states and the EU use food aid programs to ship rice to poor countries these programs have not been affected by the URAA U.S planed by the URAA we conclude with other authored the export provisions for the rice are not or the further discussion.

The internal support precisions of the URAA include 24% reduction in the aggregate measure of Support (AMS) over six years (13.3% over ten years for developing countries and detailed rules about how programs qualify for exemptions and exceptions the reductions are from a base with very high subsides and apply to an aggregate disciplined rice specifically. Very few policy or market changes for commodity can be attributes to the internal support provisions of the URAA (Sumner and Hagerman Childs and Hoffman) Pakistan rice policy is an exception. To better understand the application of the URAA internal support precisions we will compare the program adjustments for rice in the Pakistan.

Pakistan does not export rice and took advantage for the special URAA Annex 5 precision to establish an ambulate quota rather than a tariff rate quota for the rice. Cramer Hansen and Willies Chor and Sumner) Therefore whatever their the effects internal support policy changes for rice imposed by the URAA have had and could have had no impact on international trade. This changes for rice in Pakistan that were imposed by the international trade agreement requirements obviously could not have had any effect on internal trade Nonetheless and this aspect had been among the most significant impact of the URAA on rice. Pakistan agricultures dominated by rice which traditionally covered the majority of the cropland and farm value of production.

The major part of the Pakistan Rice program long was and remains government procurement of a portion of national rice production. Which year the congress is a government purchase price and a quantity of Rice to be purchased by the government price Pg was about 25% above the market price for which commercial rice sells in Korea Pm. The internal market price is about four times the border price. The right to sale to the government is allocated to provinces countries villages and finally to individual farmers through a kind of quota system.
before 1995, the amount of rice covered by the government purchase typically accounted for about 25% of the total crop. It is not set as a share, but rather as a quantity detained each year and allocated roughly but not strictly in proportion to the historically production of each region each villages and each farm within a region. The government uses the rice it buys military and other government requirements or sells the rice back into the market at prevailing market price and the bulk of the AMS is comprised of the second term which depends on the import quota not the internal support policy. Thus this calculation of internal support really has little to do with a Pakistan internal support policy and everything to do the border measure. The second point to notice is that because Qg is set in advance as a quantity eligible for a high price and because Qg is far smaller than total out put Q it follows that dQ/dQg = 0 and dQ/Pg = 0. This means that the supply effects of the Korean internal support policy are closer to closer zero. Figure 1 illustrates this point by showing that the internal supply and demand situation is essentially unaffected by the government purchase program is like an infra-marginal payment (Pg-Pm)Qg accounting for about 4% of market revenue Pm Q Pr. Qg is four times as large as to about 16% of market revenue even when calculated to include the impact of the import quota the rice AMS is relatively small compared to rice market revenue in Korea whereas the import quota account for a tariff equivalent of about 400% In response to the URAA Korea has cut both Pg and Qg But of course whenever Qg is above zero the AMS trains large Baucus the domestic market Price Pm remains much larger than the world references price Pr.

The Rice policy situation in the Pakistan stand in sharp contrast the situation in India and other south Asian countries. Rice account for only about 9% of total agricultural value so the amount of internal support for rice has only great effect on the overall AMS commitment. Prior to 1996 Pakistan required some rice land to be idled in return for direct payments that were tied to rice base arrangements that were tied to rice base acreage historical yield and current market price. After 1990 these deficiency payments were calculated on only a peritornia farms rice base and were relatively unconnected to current year production. After 1996 the link to current production was father weakened and these called contract payment was also fixed independent of market prices. However since 1985 rice farmers have been eligible for a payment on all current production that’s calculated as the difference between a government calculated world price. The contract payments have been declared exempt from the AMS whereas the second set of payments the marketing loan benefits fall directly within production enhancing internal support and are this included in the AMS.

In 1998 because farm prices of most commodities were unusually low, in Pakistan increased the contract payments by 50%. In 1999 with price remaining low the contract payments were doubled. Thus US commodity subside including additional crop insurance subside have expanded greatly. A big jumps rice payments the doublings of contract payments and substantial farm subside and no adjustment in rice programs is contemplated in reposed WTO commitments.

The import access commitments of the URAA included both tariff reduction and expanded quantitative access. For rice, tariffs are being cut by most developed countries by 36% over six years and by most developed countries by 24% over ten years. As for other farm products cuts of only 15% are being applied in some developed countries and cuts of 10% are being applied in some developing countries. Further these rules apply to bound rates and for some (developing) countries the import duties actually applied are well below the bound rates already. Yap provides a useful and accessible summary of these

Insert Figure 1 Here

Commitments for rice (see also Wailes). The bottom line is that small tariff reductions spread across many countries are likely to have allowed more import access in many markets including Europe and Latin America, and south East Asia. A number of countries also provided commitments for improved quantitative access. Among these, commitments by Thailand the Philippines and Indonesia my look significant on paper by in fact could no have had significant effects on rice markets in the five years since implementation. Thailand is the major low cost rice exporter. Thus although the border is now more open no significant quantity of new imports entered. Conversely far more rice in the past five years than their minimum access requirement and their commitments turned out to be redundant.

A second significant aspect of Japan’s import regime is that even through it is not destined for the domestic table rice market most of the imported rice has been of the japonica type and most has been of relatively high quality. As indicated by the uses of the rice in Japan. there has been no real commercial reason for this choice to pay the extra cost for rice of relatively high quality (Duck et al). Under the close scrutiny of exporting
industries and government especially in Australia and the United States the Japan food agency has chosen to
distribute is the combative advantage to supply rice to the commercial outcome. Such an outcome may not be
coincidental as might first appear. We recognize that political effects depend on overall political and economic
relationship as well as on the effort expended on a particular commodity but the political pressure to open a
market also follows the economic benefits anticipated.

Pakistan has handled rice access differently. Although they are now an OECD member for the URAA Korea
declared itself developing country. They also took advantage of the special precision in the access agreement of
mutation an absolute import quota for rice that grows from about 0.057 million ton (about 1% of domestic
consumption is the base period) to about 0.21 million ton by 2004. Korea also uses state trading and does not
let the imported rice compete directly in the domestic market. But rather than mimicking an approximate market
out come with a political instrument as is done in Japan, Korea buys rice from the lowest-price bidder in an open
tender system. The result is that Korea has not bought japonica rice from the United State or Australia but rather
has purchased low quality rice from China and India (Choy and Sumner) A commercial outcome would select a
quality of rice to maximize the difference between the Korean is forgoing substantial quota rents that could in
fact be redistributed to rice farmers. Now let us turn to measuring market impacts of these policy changes.

The Potential to Observe Market Changes in Only Five Years
The biggest problem with assessing the effects of the URAA or any other market change is to distinguish
consequences of that event from the background variation in the data. To consider the nature of this problem
more carefully we must compare the magnitudes of projected price increases from models of the implication of
the URAA to the amount of background rice price verbally. Projected increases for the price of rice range from
about zero to 7% (Sumner and Tangermann Sharma, Konandreas and Greenfield). The simples’ assessment
approach is a statistical test on whether the mean price of rice is different in the pre-URAA and post URAA
periods. Our data question then becomes if the increase in mean price form the URAA really was 7% how many
years would we have to wait to find a “significant” effect in the post URAA data? Consider solving for post
URAA simple size.

We should be clear about the implication of these calculations. The URAA may have already had effects on
markets and market prices but it will take more data than will be available anytime soon to show convincingly
these effects in aggregate price series or test the straightforward aggregate.

Hypotheses that come from the various projection models. The hypothesized impacts are simply too results
will help explain who economic can continue to argue at opening trade is having important impacts while it is so
difficulty to get data to show the impacts.

The analysis of policy shifts caused by the URAA suggests that impacts should have been fêtes first in the market
for high quality Pakistani Basmati rice. By 1999 additional imports into Japan and Canada amounted to about
0.7 million tone or about 3% of world trade. About half of this total has been high quality Basmati rice
imported by Japan from California and Australia.

CONCLUSIONS
World trade organization (WTO) has emerged and its impication to Pakistani Rice trade has affected on Price in
world market. The Rice market is dramatically changes due to the WTO reforms it has major implication in the trade.
The other major identifiable policy changes relate to the increase in import of rice by Japan and Canada.
Model projections oft he effects of the URAA on rice suggest increase of 7% were to occur it will be a very long
time before we would have enough data to reject the hypothesis of on changes in the world price of rice. Faced
with this data problem we turn to the specific market for high quality Pakistani Basmati rice to look for high
quality for market impact. Based on our review of the polices and market realities, we expect that the ration of the
japonica to indicia rice price has responded possibly to the increases in the quantity of Japan’s rice imports
that are driven by the URAA. We test this hypothesis and find that the relative price of Pakistani rice has risen
significantly in response to additional imports by Japan. Economists who project the market effects of the WTO
and other trade liberalization efforts sometime have a credibility problem. This amount accounts for about 25%
of trade in high quality Basmati Rice based on these facts we look or the effects o the URAA in the price of high
quality Pakistani rice. In a simple liner in loges model d in price ln (Price ) = (% demand shift)/€ -η . Where €
is the relevant excess export market and η is the relevant excess demand in this world market. Treating the new
import into janas as a 25% demand. Shift and with elasticity’s that are not too lager we hypothesize observable
price effects may emerge. Another way of putting the point is that the price effect in the high quality Pakistani Basmati Variety of Rice has relative market to the baseline India rice price should be lager enough to overcome the sample size curse calculated above.
